The critical flow prover (CFP) device provides a means to determine gas flow rate, \( Q \), using principles of adiabatic, frictionless compressible flow in the critical, or choked, condition.

### Principles of Operation

A compressible fluid traveling at subsonic velocity through a duct of constant cross section will increase velocity when passing through a region of reduced cross-sectional area (in this case, an orifice) to satisfy mass flow continuity. To satisfy conservation of energy, the fluid pressure at the obstruction decreases (i.e. Venturi effect).

Maximum velocity at the obstruction is limited by the rate at which pressure waves can propagate through the fluid (“the speed of sound”), and the flow will not exceed this velocity at the obstruction. Known as choking, or critical flow, the orifice velocity remains constant over a wide range of downstream pressure and temperature conditions. Since volumetric flow is proportional velocity, the volume flow rate of a choked flow can be determined based solely on upstream absolute pressure and temperature.

Critical flow will occur as the ratio of the obstruction flow area to the duct flow area approaches zero, and the ratio of upstream to downstream pressure for air, assumed to be an ideal gas, is 0.528\(^\dagger\). That is, the downstream pressure must be 0.528 times the upstream pressure (or less) in order to have critical flow at the obstruction. For example, to have critical flow with an upstream pressure of 10 MPa, the downstream pressure must be 5.28 MPa or less.

Empirically, natural gas exhibits critical flow behavior with straight-edge orifice diameters less than 60% of the pipe diameter, and ratio of absolute downstream to absolute upstream pressure between 0.56 and 0.58. For example, a subsonic natural gas flow in a 50 mm pipe at 10 MPa will be critical through a 30 mm (or smaller) orifice, and downstream pressure of 5.6 MPa or less.

The critical flow prover device ensures choked flow over a wide range of downstream pressures, allowing the use of critical flow property relationships to determine flow rate. By using critical flow properties, variability as a result of fluctuating downstream conditions is negated, allowing flow rates to be computed based solely on upstream conditions.

### Device Description

The Hawkeye Industries Critical Flow Prover consists of a tubular section, approximately 6 pipe diameters long, with a smooth inside diameter and standard 2 NPT connection on the upstream end. The opposite end features a recess, with an o-ring face-seal, for a 1/4 in. thick orifice plate, held in place by a knurled retention cap. Approximately one pipe diameter upstream of the orifice plate are a 1/2 NPT and 1/4 NPT pressure taps, suitable for gauge mounting and a thermowell.

### Operating Information

The flow rate through the CFP is determined using the following equation:

\[
Q = \frac{CP}{\sqrt{GT}}
\]

(eq. 1)

Where:

- \( Q \): Flow Rate \((10^3 \text{ ft}^3 / 24 \text{ hr} \text{ aka Mcfh}) \text{ or } 10^3 \text{ m}^3 / \text{d})\)
- \( C \): Orifice Coefficient (empirically derived, see tables 1a and 1b)
- \( P \): Absolute Upstream Pressure \( (\text{psi or MPa})\)
- \( G \): Specific Gravity of Gas (air = 1.0)
- \( T \): Absolute Upstream Temperature \( (°R \text{ or } K)\)

Note: Equation 1 assumes a perfect gas, and does not account for deviations from Boyle’s Law behavior.

### Units:

When determining flow rate in imperial units ([Mcfh], or \([10^3 \text{ ft}^3/24\text{hr}]) use the following units in Equation 1:

- \( C \): From Table 1a.\(^\dagger\)
- \( P \): pounds per square inch \([\text{psi}]\)
- \( G \): unitless
- \( T \): Rankine \( (°R)\)

---

---

Likewise, to determine flow rate in metric, or SI units ([10^3 m^3/d]), use the following units in equation 1:

- \( C \): From Table 1b.
- \( P \): Megapascals [MPa]
- \( G \): unitless
- \( T \): Kelvin [K]

**Absolute Temperature:**

Thermodynamic calculations require use of absolute temperature in computations. In imperial units, absolute temperature is measure in Rankine (°R), calculated using the following formula:

\[
\text{°R} = \text{°F} + 459.67
\]  
(eq. 2)

**Example**: 60 °F = 519.67 °R

Similarly in SI, absolute temperature is measured in Kelvin (K) and is calculated using the following formula:

\[
K = °C + 273.15
\]  
(eq. 3)

**Example**: 17 °C = 290.15 K

Tables 1 provides orifice coefficients for imperial units and metric (SI) units. The coefficients were derived from equation 1, using a known flow rate, Q, at a temperature of 60 °F [519.67 °R] and downstream pressure of 14.4 psia.

**Graphical Representation:**

The flow rate, in 10^3 ft^3/24hr (Mcfh), has been calculated at 14.4 psi and 60 °F [519.67 °R], and plotted on charts A1 through B4, with a line for each orifice size (listed on the chart margins). Chart series A is scaled to provide legible values for orifice diameters 1/4 in. and under, while the series B charts show full-scale flow values.

Similarly, the flow rates, in 10^3 m^3/d at 99.3 kPa and 16 °C [289.15 K] have been calculated, and plotted on charts C1 through D4, with a line for each orifice size (listed on the chart margins). Chart series C is scaled to provide legible values for orifice diameters 1/4 in. and under, while the series D charts show full-scale flow values.

These charts are for informational purposes only. Use of equation 1 is required for accurate flow rates from a particular application.
